1 "PROCESS AND APPARATUS FOR SLEEVE REPAIR OF PIPE LINE"

2 ABSTRACT OF THE DISCLOSURE

3 A longitudinally split cylindrical sleeve, consisting of two
4 half shells, is applied to an internally pressurized pipe, to reinforce
5 a section of the pipe wall weakened by an internal or external defect.
6 One pair of adjacent shell ends are first welded together along their
7 length with the shells in place on the pipe in a relaxed condition. The
8 other pair of adjacent shell ends are equipped with longitudinally
9 extending, outwardly projecting, attached shoulder lugs. A clamp
10 assembly is applied to the shoulder lugs to draw them together and
11 tension the sleeve about the pipe. The clamping force applied to the
12 shoulder lugs is monitored and terminated when the applied stress in the
13 sleeve is approximately equal to the stress exerted on the pipe wall by
14 the internal fluid pressure. The free ends of the shells are then
15 welded together longitudinally while in the tensioned condition. The
16 sleeve/pipe combination forms, in effect, a thick-walled cylinder. The
17 stress arising from the internal fluid pressure is distributed across
18 the cylinder. This effectively lowers the stress at the location of
19 the defect. This, in turn, eliminates the need to apply circumferential
20 fillet welds at the sleeve ends, since further deterioration of the
21 defect (which would lead to leaking of the contained fluid) is arrested.

FIELD OF THE INVENTION

This invention relates to repairing or reinforcing a cylindrical member, such as a high pressure steel fluid transmission pipe line, by engirdling it with a longitudinally split sleeve. The free ends of the sleeve are welded together longitudinally to form a collar that tightly enwraps said pipe.

The invention has an apparatus aspect, pertaining to the clamping means used to tension the sleeve halves or shells (already welded together along one pair of ends) and to hold the shells in that condition around the pipe while the remaining pair of free ends are welded together.

The invention further has a method aspect, relating to the combination of steps used to apply the tensioned sleeve.

And it has a product aspect, pertaining to the cylindrical member with the tensioned sleeve applied thereto and fixed therearound.

BACKGROUND OF THE INVENTION

The invention was originally conceived as a method for repairing steel pipe lines. While not limited to that application, it will now be discussed in connection with that specific application.

Oil and natural gas transmission pipe lines commonly develop defects in the pipe wall, usually in its outer surface. Predominantly, these defects take the form of corrosion pitting, which is initiated when the protective coating on the pipe is damaged and moisture comes into contact with the steel surface of the pipe. The resulting galvanic corrosion cell develops a string of rusty pits of varying depth. In addition to corrosion pitting, there can also be other defects such as dents, gouges, grooves, and cracks, which arise as a result of poor installation practises, third party acts, or metal fatigue during service.

1 In cases where the defect is shallow in nature, it is usual
2 to repair the existing pipe rather than to cut out and replace the
3 damaged segment.

4 The type of repair applied to a shallow defect depends on
5 factors such as its orientation, size and depth, the pipe wall thickness,
6 and the maximum operating pressure.

7 If the corrosion is not very extensive, the corrosion product
8 is simply cleaned out and the pits are filled with hardenable mastic or
9 epoxy, to restore the smooth pipe contour. The pipe segment is then
10 re-wrapped with new protective coating and placed back in service.

11 If the defect is more serious, it is common practice to
12 apply a full encirclement sleeve to engirdle the defect and reinforce
13 the pipe at the locus of the defect. The present invention is concerned
14 with this sleeve type of repair.

15 The sleeve repair procedure commences with some of the same
16 steps as those used with the minor defects. That is, the protective
17 coating is removed from the pipe segment to be repaired, the dirt and
18 corrosion products are cleaned out of the pits, and the pits are filled
19 with mastic or epoxy. Then a steel sleeve, split longitudinally into
20 two half shells, is placed around the pipe over the defect. The two
21 half shells are welded together by a longitudinal butt weld formed along
22 one pair of adjacent ends, with the shells in a relaxed condition. A
23 chain or cable is then tightened around the exterior of the sleeve using
24 a ratchet tensioner, to clamp the sleeve tightly to the pipe. When the
25 shells are clamped in this manner, a slight longitudinal gap still exists
26 between the two remaining free ends of the sleeve. A second longitudinal
27 butt weld is then applied along this gap, to join the free ends and
28 convert the sleeve into a closed collar.

1 If there is concern that a leak will subsequently develop
2 at the defect, it is common practice to apply a circumferential fillet
3 weld between the pipe and the sleeve at each end of the sleeve. In
4 this manner, a pressure tight vessel is created around the defect, to
5 contain the leak should it develop.

6 To execute the circumferential fillet welds, it is necessary
7 to heat the pipe and the sleeve to the proper welding temperature along
8 the area to be welded. In the case of liquid transmission pipe lines,
9 the presence of stationary or flowing liquids significantly affects the
10 cooling rate of circumferential fillet welds. Similarly, in the case of
11 a gas line, the segment being welded must be filled with water or the
12 like, to avoid the possibility of an explosion. The presence of the
13 liquid accelerates the cooling rate. When the cooling rate is too fast,
14 the pipe steel has a tendency to develop martensitic microstructures
15 (hard spots) along the toe of the circumferential fillet weld. This
16 condition, known as embrittlement, particularly manifests itself in the
17 older pipelines now undergoing repairs which are known to have a higher
18 carbon content than modern pipe steels.

19 Eventually, these welds can fail catastrophically by cracking
20 when they are subjected to severe external stresses imposed by a variety
21 of soil conditions, such as poor backfill compaction following sleeve
22 installation, soil movement from freeze-thaw cycles, and insufficient
23 cover under travelled areas.

24 This problem with circumferential sleeve welding is such
25 that many pipe line companies do not allow this type of sleeve repair
26 to be made on their pipe lines, preferring to cut out and replace the
27 damaged segment instead.

1 To provide a feeling to the reader for the high incidence
2 of these repairs, a pipe line company in Alberta recently replaced a 1/2
3 mile section of pipe that had 16 sleeve repairs in place along its length.
4 However, in balance it needs to be said that there are other long seg-
5 ments of line that are free of sleeve repairs.

6 In summary, the repairs to be made are numerous, they have
7 involved for decades the use of the repair sleeve procedure previously
8 described, and the problem connected with the circumferential fillet
9 weld has not heretofore been solved.

10 SUMMARY OF THE INVENTION

11 The present invention has the objective of providing a full
12 encirclement sleeve that so reinforces and joins with the wall of the
13 cylindrical member being encircled that the two together, in effect,
14 become a short thick-walled cylinder. The stress, arising from fluid
15 pressure within the cylindrical member, is distributed throughout the
16 thick-walled cylinder. As a result, the stress level associated with
17 the defect is reduced. This reduction in stress level is sufficient so
18 that the troublesome circumferential welds become unnecessary.

19 More particularly, a longitudinal (lap) weld is first applied
20 in the usual manner along two adjacent ends of the sleeve shells. Each
21 shell is equipped with an outwardly protruding and rigidly attached
22 shoulder lug adjacent its remaining free end. A clamp is used to draw
23 the shoulder lugs together, thereby tensioning the sleeve around the
24 cylindrical member (usually a pipe) until the stress level in the sleeve
25 is substantially equal to that present in the pipe wall (said stress in
26 the wall arising from the fluid pressure within the pipe). At this point,
27 the free ends of the sleeves are welded together, to complete the instal-
28 lation of the sleeve.

1 By using a clamp whose applied force can be measured, such
 2 as a hydraulic clamp having cylinder means, it is possible to monitor
 3 the closing or tensioning force being applied to the shoulder lugs,
 4 using a gauge. Therefore it is possible to accurately apply a
 5 circumferential tensioning stress to the sleeve that substantially
 6 satisfies the equation:

$$7 \quad S = \frac{PD}{2t} \quad (1)$$

8 where S = the circumferential stress to be
 9 applied in pounds/inch²

10 P = the internal pressure of the pipe
 11 in pounds/inch²

12 D = the outer diameter of the emplaced
 13 sleeve, in inches

14 t = the wall thickness of the thick-walled
 15 cylinder created by the combination of
 16 the pipe and encircling sleeve, in inches.

17 In summary then, the sleeve is pre-tensioned before the
 18 final longitudinal weld is applied. The pre-tensioning is conducted
 19 using means whose closing force can be monitored, so that it is known
 20 when a desired stress level in the sleeve has been achieved. This
 21 stress level is selected so that, when the last weld is applied, the
 22 sleeve will thereafter in conjunction with the cylindrical member
 23 in effect form a thick-walled cylinder and share the stress acting on the
 24 cylindrical member. Preferably, the pre-tensioning stress applied
 25 satisfies equation (1).

1 To accomplish these ends, there is provided a novel
2 clamp assembly for tensioning the sleeve. The clamp assembly
3 comprises a preferably rectangular frame forming a generally
4 central opening or window. The window is configured to
5 permit the sleeve shoulder lugs to project therethrough. One
6 end of the frame bears against the rear surface of the first
7 shoulder lug. Means, such as a hydraulic cylinder or a
8 tensioning screw, is mounted on the other end of the frame
9 for biasing the second shoulder lug toward the first lug.
10 The frame and biasing means thus together cooperate to fix
11 the first lug while forcing the second lug toward it, thereby
12 tensioning the sleeve around the pipe. The two free ends of
13 the sleeve are left exposed by the window, so that the last
14 weld may be applied. Restraining members are provided to
15 connect the frame with each shoulder lug, to prevent the
16 moment exerted by the biasing means on each lug from rotating
17 it inwardly.

18 Broadly stated, the invention in one aspect
19 comprises, in combination, an internally pressurized and
20 stressed high pressure fluid transmission pipe line having a
21 surface defect; and a pair of externally applied full
22 encirclement shells forming a sleeve extending around the
23 pipe line at the defect, said shells having first been
24 longitudinally welded together along their second ends while
25 on the pipe line, said shells having an inside diameter
26 substantially equal to the outside diameter of the pipeline,
27 so that substantially the entire inside surface of the sleeve
28 is in contact with the outside surface of the pipe line, said
29 shells having a length such that their first ends do not come
30 into abutment when the shells are emplaced on the pipe line

1 and their second ends are welded together, said shells having
2 been tensioned by drawing their first ends together
3 sufficiently, without bringing them into abutment, so that
4 the stress in the shells is substantially the same as that in
5 the underlying wall segment of the pipeline, said shells
6 having been longitudinally welded together along their first
7 ends while so tensioned.

8 In another broad aspect, the invention comprises a
9 process for reinforcing an internally pressurized and
10 stressed cylindrical member, said member having a defect in
11 its wall, comprising: mounting a full encirclement sleeve,
12 comprising a pair of discrete sleeve shells, around the
13 member over the defect, each shell having first and second
14 ends and an outwardly projecting lug attached thereto
15 adjacent the first end of the shell, said lug extending
16 substantially the full width of said first end, said first
17 ends of the shells being overlapped, said shells being of an
18 internal diameter substantially equal to the outside diameter
19 of the cylindrical member and having a length such that, when
20 their second ends are welded together and their first ends
21 are pulled toward each other, tension will be applied to the
22 shells without the first ends of the shells coming into
23 abutment; welding the second ends of the shells together;
24 applying increasing clamp force to the lugs to draw them
25 toward each other and tension the sleeve, whereby
26 substantially the entire internal surfaces of the shells are
27 in contact with the outside surface of the cylindrical
28 member, said force being generally evenly applied along the
29 length of the lugs; simultaneously restraining the lugs
30 against inward pivoting movement to maintain the sleeve ends

1237682

1 in substantial alignment; measuring the force being applied
2 and stopping the drawing together of the lugs when the sleeve
3 has been tensioned a pre-determined amount and stress in the
4 underlying portion of the cylindrical member has been
5 reduced; maintaining said sleeve in said tensioned condition
6 and welding the first ends of the shells together; and
7 relaxing said clamping force.

1 The specific best mode of the invention is now described,
2 for exemplification, in connection with the following drawings.

3 DESCRIPTION OF THE DRAWINGS

4 Figure 1 is a side view of the sleeve having the shoulder lugs
5 mounted thereon;

17 Figure 8 is a schematic illustration of the positioning of
18 the internal and external strain gauges on the test pipe.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Figure 1 shows a conventional, longitudinally split sleeve 1 comprising two semi-circular, steel shells 2, 3. The shells 2, 3 are formed at their end edges with a lap joint configuration.

The shells 2, 3 are placed on the pipe 4 to encircle the defect to be repaired. As a first step, they are welded together longitudinally along their rear ends 5, 6 in conventional fashion.

A pair of elongate, outwardly projecting shoulder lugs 7, 8 are positioned along the front ends 9, 10 of the shells 2, 3. These shoulder lugs 7, 8 are each affixed to their respective shell, as with welds 11. Each shoulder lug 7, 8 provides a rear bearing surface 12, 13 against which the clamp assembly 14 will bear.

The clamp assembly 14 comprises a rectangular, collar-like, steel frame 15 having a rectangular opening 16 formed therein.

Along the upper end of the opening 16, the upper end portion 19 of the frame 15 provides a clamping surface 17 for locking against the rear bearing surface 13 of the shoulder member 8.

Along the lower end of the opening 16, a base plate 20 is affixed by bolts 21 to the lower end portion 22 of the frame 15. A plurality of vertically extending hydraulic cylinders 23 are supported by the base plate 20 and are held in position by straps 24.

A pair of vertically extending guide rails 25 are formed along the inner surface of the side portions 26, 27 of the frame 15. A horizontal push bar 28 is supported by the pistons 29 of the cylinders 23. The push bar 28 has milled slots in each end that engage with the guide rails 25. Thus the cylinders 23 can slide the push bar 28 up and down in the frame opening 16 along the guide rails 25, to bias the lower shoulder member 7 of the sleeve 1 toward the upper shoulder member 8.

1 Each of the clamping beam 17 and push bar 28 carries a
2 restraining member 32, 33 respectively for over-arching and engaging
3 the shoulder lug 7 or 8 associated therewith, to restrain the shoulder
4 lug against inward rotational movement. When the clamping bar 17 and
5 push bar 28 bear against the shoulder lugs 8, 7, the resultant moment
6 would tend to rotate the outer ends of the shoulder lugs downwardly
7 and inwardly, thus applying additional load to the pipe 4; the restrain-
8 ing members 32, 33 function to prevent such rotation from taking place.

9 A hydraulic pump is used to expand the cylinders 23. A
10 pressure gauge is attached to the pump, to provide a measure of the
11 force being applied to the shoulder members 7,8.

12 Example

13 To demonstrate the invention, a repair was made on a test
14 length of pipe having a defect formed therein.

15 More particularly, a 15' length of 24" diameter x 0.344"
16 thickness line pipe was provided. The pipe was formed of API Grade
17 5L-B steel and was closed at its ends.

18 The test pipe was equipped with strain gauges on its inner
19 and outer surfaces. The locations and orientations of the gauges are
20 indicated in Figure 8. A description of the gauges is given in Table 1.

TABLE I
Gauge Locations

Gauge No.	Orientation	Monitors
2	Hoop	Internal surface of pipe 90 degrees from the weld seam and remote from the sleeve
3	Longitudinal	Internal pipe surface stress at the edge of the sleeve
6	Hoop	Pipe internal surface stress under the sleeve
7	Hoop	Pipe internal surface stress under the sleeve
10	Hoop	Sleeve stress about 6" from final weld
11	Hoop	Sleeve stress about 12" from final weld
12	Hoop	Sleeve stress about 24" from final weld
13	Hoop	Sleeve stress about 24" from final weld
14	Hoop	Sleeve stress about 12" from final weld
15	Hoop	Sleeve stress about 6" from final weld
16	Longitudinal	External pipe surface at edge of sleeve
17	Longitudinal	External pipe surface at edge of sleeve
19	Longitudinal	External pipe surface at edge of sleeve.

A 12" wide x .5" thick x 24" internal diameter sleeve of API 516 Grade 70 carbon steel was used. The sleeve was in the form of 2 semi-circular shells.

The pipe was pressured internally to 500 psi, without the sleeve in place. The stress values noted are set forth in Table II.

TABLE II

Pipe Wall Stress Values Measured Prior to Sleeve InstallationPipe Pressured to 500 psi

<u>Gauge No.</u>	<u>Stress/Strain Value psi*</u>	<u>Zero Check Value psi**</u>
2 internal pipe wall	12150 (remote from	- 240
stress - hoop	sleeve)	
3 internal pipe wall	13350 (at sleeve	- 750
stress - longitudinal	edge)	
6 internal pipe wall	14340 (under sleeve)	- 90
stress - hoop		
7 internal pipe wall	13740 (under sleeve)	-300
stress - hoop		

* Stress/strain values are strain gauge readings converted to stress by assuming an elastic modulus of 30×10^6 psi.

Pipe pressure was reduced to zero to check the accuracy of the strain gauges (zero check)

** The zero check readings should read between 0 and ± 1000 psi to confirm that the strain gauge is functioning within the limits of accuracy.

The pipe was then repressured to 500 psi in preparation of sleeve installation.

1 The pipe surface over the defect was cleaned and a lubricant
2 was applied to the sleeve area, to facilitate seating of the shells.
3 The shells were positioned around the pipe over the defect area with
4 the shoulder lugs adjacent each other. The sleeve gap at the shoulder
5 lugs was maintained at .125" by means of a spacing plate positioned
6 between them. The shells were then snugged down onto the pipe using a
7 chain type ratchet tensioner and the back weld was applied. After the
8 weld cooled, the spacing plate was removed.

9 The frame 15 was then fitted over the shoulder lugs 7, 8
10 and hydraulic pressure was applied to the push bar 28, until the cylinder
11 pressure reached 4500 psi, to tension the sleeve 1 by biasing the
12 lower shoulder lug 7 toward the upper shoulder lug 8, said shoulder lug
13 8 being locked in place by the upper end 19 of the frame. The 4500 psi
14 value used was obtained by a calculation in accordance with equation (1),
15 to offset the internal pressure of 500 psi which was maintained in the
16 pipe during installation of the sleeve. This internal pressure was later
17 increased to 1000 psi after welding was complete. The stress values
18 recorded in connection with the test installation are set forth in
19 Table III.

TABLE III

Pipe and Sleeve Stress Values Measured During and
After Sleeve Installation

Gauge	500 PSI Sleeve Tensioned	500 PSI Sleeve Installed	1000 PSI Sleeve Installed	0 PSI Sleeve Installed
2	11640	11790	25800	- 3360

16	7080	8220	14640	4140
17	4950	5160	10140	1860
19	4200	7530	14910	1110

Negative values denote compression.

Gauge 2 measures the internal surface tension remote from the sleeve, and is used as a reference of unrestrained pipe wall stress.

Gauge 3 measures the longitudinal pipe surface tension at the edge of the sleeve.

Gauges 6 and 7 measure the internal pipe surface tension under the sleeve.

Note: tension measured by these gauges will decrease as the pipe wall stress transfers to the sleeve due to the applied hydraulic force of the clamp. Compare the readings of gauge 2 with gauges 6 and 7 after sleeve installation at internal pipe pressures of 500 psi and 1000 psi to note the stress reduction in the pipe wall.

1 Gauges 10 to 15 indicate hoop tension on the outer surface
2 of the sleeve at various distances from the clamping point and show
3 the stress distribution around the sleeve.

4 Gauges 16, 17 and 19 measure longitudinal surface tension in
5 the pipe near the edge of the sleeve and the values shown indicate the
6 even distribution of stress to the sleeve without excessive localized
7 stress in the pipe wall.

8 The scope of the invention is set forth in the claims which
9 follow. It will be noted that the clamp assembly has been described
10 with respect to a specific embodiment having a hydraulically driven
11 slidable push bar acting against one shoulder lug while the other
12 shoulder lug is held stationary by a rigid frame connected with the
13 cylinder means. However it would be feasible to use two driven slidable
14 push bars to act simultaneously from above and below on the shoulder
15 lugs and other biasing means, such as a screw, could be used; the clamp
16 assembly is to be interpreted to encompass such alternative embodiments.

1 THE EMBODIMENTS OF THE INVENTION IN WHICH AN
2 EXCLUSIVE PROPERTY OR PRIVILEGE IS CLAIMED ARE DEFINED AS
3 FOLLOWS:

4 1. In combination:

5 an internally pressurized and stressed high
6 pressure fluid transmission pipe line having a surface
7 defect; and

8 a pair of externally applied full encirclement
9 shells forming a sleeve extending around the pipe line at the
10 defect, said shells having first been longitudinally welded
11 together along their second ends while on the pipe line, said
12 shells having an inside diameter substantially equal to the
13 outside diameter of the pipeline, so that substantially the
14 entire inside surface of the sleeve is in contact with the
15 outside surface of the pipe line, said shells having a length
16 such that their first ends do not come into abutment when the
17 shells are emplaced on the pipe line and their second ends
18 are welded together, said shells having been tensioned by
19 drawing their first ends together sufficiently, without
20 bringing them into abutment, so that the stress in the shells
21 is substantially the same as that in the underlying wall
22 segment of the pipeline, said shells having been
23 longitudinally welded together along their first ends while
24 so tensioned.

1 2. A process for reinforcing an internally
2 pressurized and stressed cylindrical member, said member
3 having a defect in its wall, comprising:

4 mounting a full encirclement sleeve, comprising a
5 pair of discrete sleeve shells, around the member over the
6 defect, each shell having first and second ends and an
7 outwardly projecting lug attached thereto adjacent the first
8 end of the shell, said lug extending substantially the full
9 width of said first end, said first ends of the shells being
10 overlapped, said shells being of an internal diameter
11 substantially equal to the outside diameter of the
12 cylindrical member and having a length such that, when their
13 second ends are welded together and their first ends are
14 pulled toward each other, tension will be applied to the
15 shells without the first ends of the shells coming into
16 abutment;

17 welding the second ends of the shells together;

18 applying increasing clamp force to the lugs to draw
19 them toward each other and tension the sleeve, whereby
20 substantially the entire internal surfaces of the shells are
21 in contact with the outside surface of the cylindrical
22 member, said force being generally evenly applied along the
23 length of the lugs;

24 simultaneously restraining the lugs against inward
25 pivoting movement to maintain the sleeve ends in substantial
26 alignment;

1 measuring the force being applied and stopping the
2 drawing together of the lugs when the sleeve has been
3 tensioned a pre-determined amount and stress in the
4 underlying portion of the cylindrical member has been
5 reduced;

6 maintaining said sleeve in said tensioned condition
7 and welding the first ends of the shells together; and
8 relaxing said clamping force.

9 3. A process for reinforcing an internally
10 pressurized and stressed high pressure fluid transmission
11 pipe line , said line having a defect in its wall,
12 comprising:

13 mounting a full encirclement sleeve, comprising a
14 pair of discrete sleeve shells, around the pipe line over the
15 defect, each shell having first and second ends and an
16 outwardly projecting lug attached thereto adjacent the first
17 end of the shell, said lug extending substantially the full
18 width of said first end, said first ends of the shells being
19 overlapped, said shells being of an internal diameter
20 substantially equal to the outside diameter of the pipe line
21 and having a length such that, when their second ends are
22 welded together and their first ends are pulled toward each
23 other, tension will be applied to the shells without the
24 first ends of the shells coming into abutment;

25 welding the second ends of the shells together;

1 applying increasing hydraulically induced clamping
2 force to the lugs to draw them toward each other and tension
3 the sleeve, whereby substantially the entire internal
4 surfaces of the shells are in contact with the outside
5 surface of the pipe line, said force being generally evenly
6 applied along the length of the lugs;

7 simultaneously restraining the lugs against inward
8 pivoting movement to maintain the sleeve ends in alignment;

9 measuring the force being applied as it is
10 increased and stopping the drawing together of the lugs when
11 the sleeve has been tensioned sufficiently so that the stress
12 condition in the sleeve is substantially the same as that in
13 the underlying portion of the pipe wall;

14 maintaining said sleeve in said tensioned condition
15 and welding the first ends of the shells together; and
16 relaxing said clamping force.
